

Operating System Security CS 239 Computer Security February 26, 2007

CS 236, Winter 2007

Lecture 10
Page 1

Outline

- Introduction
- Memory protection
- Interprocess communications protection
- File protection

CS 236, Winter 2007

Lecture 10
Page 2

Introduction

- Operating systems provide the lowest layer of software visible to users
- Operating systems are close to the hardware
 - Often have complete hardware access
- If the operating system isn't protected, the machine isn't protected
- Flaws in the OS generally compromise all security at higher levels

CS 236, Winter 2007

Lecture 10
Page 3

Why Is OS Security So Important?

- The OS controls access to application memory
- The OS controls scheduling of the processor
- The OS ensures that users receive the resources they ask for
- If the OS isn't doing these things securely, practically anything can go wrong
- So almost all other security systems must assume a secure OS at the bottom

CS 236, Winter 2007

Lecture 10
Page 4

Single User Vs. Multiple User Machines

- The majority of today's computers usually support a single user
 - Sometimes one at a time, sometimes only one ever
- Some computers are still multi-user
 - Mainframes
 - Servers
 - Network-of-workstation machines
- Single user machines often run multiple processes, though

CS 236, Winter 2007

Lecture 10
Page 5

Server Machines Vs. General Purpose Machines

- Most server machines provide only limited services
 - Web page access
 - File access
 - DNS lookup
- Security problems are simpler for them
- Some machines still provide completely general service, though
- And many server machines can run general services . . .

CS 236, Winter 2007

Lecture 10
Page 6

Downloadable Code and Single User Machines

- Applets and other downloaded code should run in a constrained mode
- Using access control on a finer granularity than the user
- Essentially the same protection problem as multiple users

CS 236, Winter 2007

Lecture 10
Page 7

Mechanisms for Secure Operating Systems

- Most operating system security is based on separation
 - Keep the bad guys away from the good stuff
 - Since you don't know who's bad, separate most things

CS 236, Winter 2007

Lecture 10
Page 8

Separation Methods

- Physical separation
 - Different machines
- Temporal separation
 - Same machine, different times
- Logical separation
 - HW/software enforcement
- Cryptographic separation

CS 236, Winter 2007

Lecture 10
Page 9

The Problem of Sharing

- Separating stuff is actually pretty easy
- The hard problem is allowing controlled sharing
- How can the OS allow users to share exactly what they intend to share?
 - In exactly the ways they intend

CS 236, Winter 2007

Lecture 10
Page 10

Levels of Sharing Protection

- None
- Isolation
- All or nothing
- Access limitations
- Limited use of an object

CS 236, Winter 2007

Lecture 10
Page 11

Protecting Memory

- Most general purpose systems provide some memory protection
 - Logical separation of processes that run concurrently
- Usually through virtual memory methods
- Originally arose mostly for error containment, not security

CS 236, Winter 2007

Lecture 10
Page 12

Security Aspects of Paging

- Main memory is divided into page frames
- Every process has an address space divided into logical pages
- For a process to use a page, it must reside in a page frame
- If multiple processes are running, how do we protect their frames?

CS 236, Winter 2007

Lecture 10
Page 13

Protection of Pages

- Each process is given a page table
 - Translation of logical addresses into physical locations
- All addressing goes through page table
 - At unavoidable hardware level
- If the OS is careful about filling in the page tables, a process can't even name other processes' pages

CS 236, Winter 2007

Lecture 10
Page 14

Security Issues of Page Frame Reuse

- A common set of page frames is shared by all processes
- The OS switches ownership of page frames as necessary
- When a process acquires a new page frame, it used to belong to another process
 - Can the new process read the old data?

CS 236, Winter 2007

Lecture 10
Page 15

Special Interfaces to Memory

- Some systems provide a special interface to memory
- If the interface accesses physical memory,
 - And doesn't go through page table protections,
 - Attackers can read the physical memory
 - Then figure out what's there and find what they're looking for

CS 236, Winter 2007

Lecture 10
Page 16

Protecting Interprocess Communications

- Operating systems provide various kinds of interprocess communications
 - Messages
 - Semaphores
 - Shared memory
 - Sockets
- How can we be sure they're used properly?

CS 236, Winter 2007

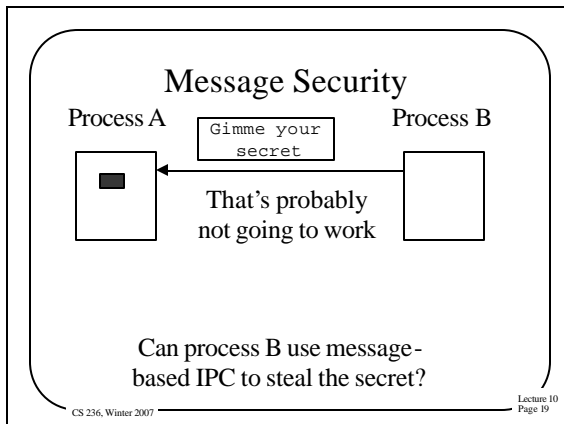

Lecture 10
Page 17

IPC Protection Issues

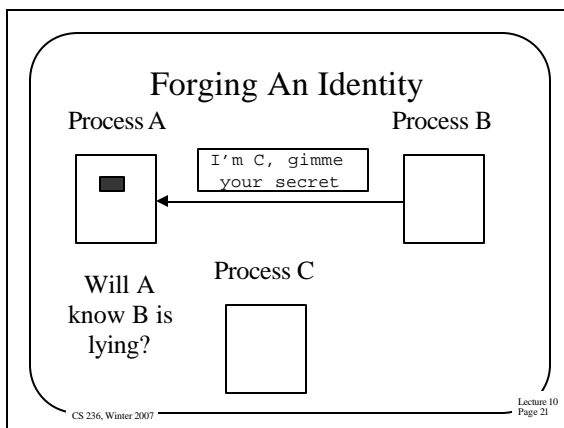

- How hard it is depends on what you're worried about
- For the moment, let's say we're worried about one process improperly using IPC to get info from another
 - Process A wants to steal information from process B
- How would process A do that?

CS 236, Winter 2007

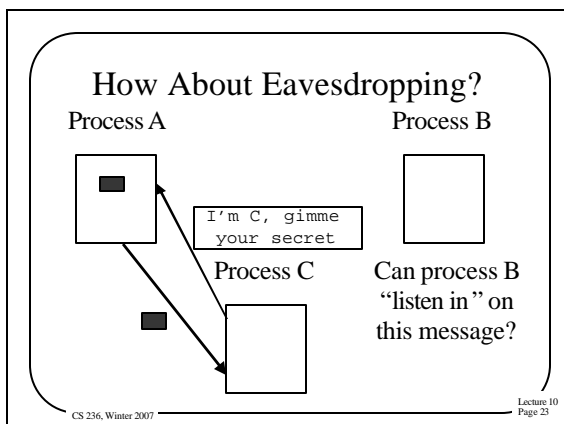

Lecture 10
Page 18

- ### How Can B Get the Secret?
- He can convince the system he's A
 - A problem for authentication
 - He can break into A's memory
 - That doesn't use message IPC
 - And is handled by page tables
 - He can forge a message from someone else to get the secret
 - He can "eavesdrop" on someone else who gets the secret
- Lecture 10
Page 20

- ### Operating System Protections
- The operating system knows who each process belongs to
 - It can tag the message with the identity of the sender
 - If the receiver cares, he can know the identity
- Lecture 10
Page 22

- ### What's Really Going on Here?
- On a single machine, what is a message send, really?
 - A message is copied from a process buffer to an OS buffer
 - Then from the OS buffer to another process' buffer
 - If attacker can't get at processes' internal buffers and can't get at OS buffers, he can't "eavesdrop"
- Lecture 10
Page 24

Other Forms of IPC

- Semaphores, sockets, shared memory, RPC
- Pretty much all the same
 - Use system calls for access
 - Which belong to some process
 - Which belongs to some principal
 - OS can check principal against access control permissions at syscall time

CS 236, Winter 2007

Lecture 10
Page 25

So When Is It Hard?

- Always possible that there's a bug in the operating system
 - Allowing masquerading, eavesdropping, etc.
 - Or, if the OS itself is compromised, all bets are off
- What if the OS has to prevent cooperating processes from sharing information?

CS 236, Winter 2007

Lecture 10
Page 26

The Hard Case

Process A

Process B

Process A wants to tell the secret to process B
But the OS has been instructed to prevent that
Can the OS prevent A and B from colluding
to get the secret to B?

CS 236, Winter 2007

Lecture 10
Page 27

Dangers for Operating System Security

- Bugs in the OS
 - Not checking security, allowing access to protected resources, etc.
- Privileged users and roles
 - Superusers often can do anything
- Untrusted applications and overly broad security domains

CS 236, Winter 2007

Lecture 10
Page 28

File Protection

- How do we apply these access protection mechanisms to a real system resource?
- Files are a common example of a typically shared resource
- If an OS supports multiple users, it needs to address the question of file protection

CS 236, Winter 2007

Lecture 10
Page 29

Unix File Protection

- A model for protecting files developed in the 1970s
- Still in very wide use today
 - With relatively few modifications
- To review, three subjects
 - Owner, group, other
- and three modes
 - Read, write, execute
 - Sometimes these have special meanings

CS 236, Winter 2007

Lecture 10
Page 30

Setuid/Setgid Programs

- Unix mechanisms for changing your user identity and group identity
- Either indefinitely or for the run of a single program
- Created to deal with inflexibilities of the Unix access control model
- But the source of endless security problems

CS 236, Winter 2007

Lecture 10
Page 31

Why Are Setuid Programs Necessary?

- The print queue is essentially a file
- Someone must own that file
- How will other people put stuff in the print queue?
 - Without making the print queue writeable for all purposes
- Typical Unix answer is run the printing program setuid
 - To the owner of the print queue

CS 236, Winter 2007

Lecture 10
Page 32

Why Are Setuid Programs Dangerous?

- Essentially, setuid programs expand a user's security domain
- In an encapsulated way
 - Abilities of the program limit the operations in that domain
- Need to be damn sure that the program's abilities are limited

CS 236, Winter 2007

Lecture 10
Page 33

Some Examples of Setuid Dangers

- Setuid programs that allow forking of a new shell
- Setuid programs with powerful debugging modes
- Setuid programs with “interesting” side effects
 - E.g., `lpr` options that allow file deletion

CS 236, Winter 2007

Lecture 10
Page 34

Domain and Type Enforcement

- A limited version of capabilities
- Meant to address the dangers of setuid
- Allows system to specify security domains
 - E.g., the printing domain
- And to specify data types
 - E.g., the printer type

CS 236, Winter 2007

Lecture 10
Page 35

Using DTE

- Processes belong to some domain
 - Can change domains, under careful restrictions
- Only types available to that domain are accessible
 - And only in ways specified for that domain

CS 236, Winter 2007

Lecture 10
Page 36

A DTE Example

- Protecting the FTP daemon from buffer overflow attacks
- Create an FTP domain
- Only the FTP daemon and files in the FTP directory can be executed in this domain
 - And these executables may not be written within this domain
- Executing the FTP daemon program automatically enters this domain

CS 236, Winter 2007

Lecture 10
Page 37

What Happens On Buffer Overflow?

- The buffer overflow attack allows the attacker to request execution of an arbitrary program
 - Say, `/bin/sh`
- But the overflowed FTP daemon program was in the FTP domain
 - And still is
- `/bin/sh` is of a type not executable from this domain
 - So the buffer overflow can't fork a shell

CS 236, Winter 2007

Lecture 10
Page 38

Encrypted File Systems

- Data stored on disk is subject to many risks
 - Improper access through OS flaws
 - But also somehow directly accessing the disk
- If the OS protections are bypassed, how can we protect data?
- How about if we store it in encrypted form?

CS 236, Winter 2007

Lecture 10
Page 39

An Example of an Encrypted File System

Encrypted
data on
disk

Issues for encrypted file systems:
When does the cryptography occur?
Where does the key come from?
What is the granularity of cryptography?

CS 236, Winter 2007

Lecture 10
Page 40

When Does Cryptography Occur?

- Transparently when user opens file?
 - In disk drive?
 - In OS?
 - In file system?
- By explicit user command?
 - Or always, implicitly?
- How long is the data decrypted?
- Where does it exist in decrypted form?

CS 236, Winter 2007

Lecture 10
Page 41

Where Does the Key Come From?

- Provided by human user?
- Stored somewhere in file system?
- Stored on a smart card?
- Stored in the disk hardware?
- Stored on another computer?
- Where and for how long do we store the key?

CS 236, Winter 2007

Lecture 10
Page 42

What Is the Granularity of Cryptography?

- An entire file system?
- Per file?
- Per block?
- Consider both in terms of:
 - How many keys?
 - When is a crypto operation applied?

CS 236, Winter 2007

Lecture 10
Page 43

What Are You Trying to Protect Against With Crypto File Systems?

- Unauthorized access by improper users?
 - Why not just access control?
- The operating system itself?
 - What protection are you really getting?
- Someone who accesses the device not using the OS?
 - A realistic threat in your environment?
- Data transfers across a network?
 - Why not just encrypt while in transit?

CS 236, Winter 2007

Lecture 10
Page 44

Full Disk Encryption

- All data on the disk is encrypted
- Data is encrypted/decrypted as it enters/leaves disk
- Primary purpose is to prevent improper access to stolen disks
 - Designed mostly for laptops

CS 236, Winter 2007

Lecture 10
Page 45

An Example of Full Disk Encryption

- Seagate's newly announced Momentus 5400 FDE product
- Hardware encryption for entire disk
 - Using Triple-DES
- Key accessed via user password
 - Possibly at boot time
 - Possibly via TPM techniques
 - Claims 57.6 Mbytes/sec transfer rate
 - But not in most recent data sheets . . .
- Product not quite for sale yet
 - And no dates I've seen for when it will be
 - Some details of how things really work not too clear

CS 236, Winter 2007

Lecture 10
Page 46
