## Certificates

- A ubiquitous form of authentication
- Generally used with public key cryptography
- A signed electronic document proving you are who you claim to be
- Often used to help distribute other keys

#### Public Key Certificates

- The most common kind of certificate
- Addresses the biggest challenge in widespread use of public keys
  - How do I know whose key it is?
- Essentially, a copy of your public key signed by a trusted authority
- Presentation of the certificate alone serves as authentication of your public key

## Implementation of Public Key Certificates

- Set up a universally trusted authority
- Every user presents his public key to the authority
- The authority returns a certificate

-Containing the user's public key signed by the authority's private key

• In essence, a special type of key server

## Checking a Certificate

- Every user keeps a copy of the authority's public key
- When a new user wants to talk to you, he gives you his certificate
- Decrypt the certificate using the authority's public key
- You now have an authenticated public key for the new user
- Authority need not be checked on-line

#### Scaling Issues of Certificates

- If there are 1-2 billion Internet users needing certificates, can one authority serve them all?
- Probably not
- So you need multiple authorities
- Does that mean everyone needs to store the public keys of all authorities?

#### **Certification Hierarchies**

- Arrange certification authorities hierarchically
- Single authority at the top produces certificates for the next layer down
- And so on, recursively

## Using Certificates From Hierarchies

- I get a new certificate
- I don't know the signing authority
- But the certificate also contains that authority's certificate
- Perhaps I know the authority who signed this authority's certificate

#### Extracting the Authentication

- Using the public key of the higher level authority,
  - Extract the public key of the signing authority from the certificate
- Now I know his public key, and it's authenticated
- I can now extract the user's key and authenticate it

## Certification Hierarchies Reality

- Not really what's used
  - -For the most part
- Instead, we rely on large numbers of independent certifying authorities
  - -Exception is that each of them may have internal hierarchy
- Essentially, a big list
- Is this really better?

# Certificates and Trust

- Ultimately, the point of a certificate is to determine if something is trusted
  - Do I trust the request enough to perform some financial transaction?
- So, Trustysign.com signed this certificate
- How much confidence should I have in the certificate?

## Potential Problems in the Certification Process

- What measures did Trustysign.com use before issuing the certificate?
- Is the certificate itself still valid?
- Is Trustysign.com's signature/ certificate still valid?
- Who is trustworthy enough to be at the top of the hierarchy?

## Trustworthiness of Certificate Authority

- How did Trustysign.com issue the certificate?
- Did it get an in-person sworn affidavit from the certificate's owner?
- Did it phone up the owner to verify it was him?
- Did it just accept the word of the requestor that he was who he claimed to be?
- Has authority been compromised?

## What Does a Certificate Really Tell Me?

- That the certificate authority (CA) tied a public/private key pair to identification information
- Generally doesn't tell me why the CA thought the binding was proper
- I may have different standards than that CA

## Another Big Problem

- Things change
  - -E.g., 2012 compromise of Adobe private keys
- One result of change is that what used to be safe or trusted isn't any more
- If there is trust-related information out in the network, what will happen when things change?

CS 236 Online

#### Revocation

- A general problem for keys, certificates, access control lists, etc.
- How does the system revoke something related to trust?
- In a network environment
- Safely, efficiently, etc.
- Related to revocation problem for capabilities

#### Revisiting Our Example

Someone discovers that has obtained a false certificate for

How does Alice make sure that she's not accepting 's false certificate?

## Realities of Certificates

- Most OSes come with set of "pre-trusted" certificate authorities
- System automatically processes (i.e., trusts) certificates they sign
- Usually no hierarchy
- If not signed by one of these, present it to the user

– Who always accepts it . . .

## An Example

- Firefox web browser
- Makes extensive use of certificates to validate entities
  - -As do all web browsers
- Comes preconfigured with several certificate authorities
  - -Over 200 of them

## Firefox Preconfigured Certificate Authorities

- Some you'd expect:
  Microsoft, RSA Security, Verisign, etc.
- Some you've probably never heard of:
  - Unizeto Sp. z.o.o., Netlock Halozatbiztonsagi Kft.,Chungwa Telecom Co. Ltd.

## The Upshot

- If Netlock Halozatbiztonsagi Kft. says someone's OK, I trust them
  - –I've never heard of Netlock
    Halozatbiztonsagi Kft.
  - –I have no reason to trust Netlock Halozatbiztonsagi Kft.
  - -But my system's security depends on them

CS 236 Online

## The Problem in the Real World

- In 2011, a Dutch authority (DigiNotar) was compromised
- Attackers generated lots of bogus certificates signed by DigiNotar
  - -"Properly" signed by that authority

-For popular web sites

• Until compromise discovered, everyone trusted them

CS 236 Online

## Effects of DigiNotar Compromise

- Attackers could transparently redirect users to fake sites
  - -What looked like Twitter was actually attacker's copycat site
- Allowed attackers to eavesdrop without any hint to users
- Apparently used by authorities in Iran to eavesdrop on dissidents

CS 236 Online —

## How Did the Compromise Occur?

- DigiNotar had crappy security
  - Out-of date antivirus software **But how**
  - -Poor software patching
  - Weak passwords
  - No auditing of logs

were you

- supposed to know that?
- Poorly designed local network
- A company providing security services paid little attention to security

#### Another Practicality

- Certificates have expiration dates
  - -Important for security
  - -Otherwise, long-gone entities would still be trusted
- But perfectly good certificates also expire
  - -Then what?

#### The Reality of Expired Certificates

- When I hear my server's certificate has expired, what do I do?
  - –I trust it anyway
  - -After all, it's my server
- But pretty much everyone does that
  For pretty much every certificate
- Not so secure

CS 236 Online

## The Core Problem With Certificates

- Anyone can create some certificate
- Typical users have no good basis for determining whose certificates to trust
  - -They don't even really understand what they mean
- Therefore, they trust almost any certificate

## Should We Worry About Certificate Validity?

- Starting to be a problem
  - Stuxnet is one example
  - Compromise of DigiNotar and Adobe also
  - Increasing incidence of improper issuance, like
    Verisign handing out Microsoft certificates
- Not the way most attackers break in today
- With all their problems, still not the weakest link
  - But now being exploited, mostly by most sophisticated adversaries
