Application Review

- Reviewing a mature (possibly complete) application
- A daunting task if the system is large
- And often you know little about it
 - Maybe you performed a design review
 - Maybe you read design review docs
 - Maybe less than that
- How do you get started?

Need to Define a Process

- Don't just dive into the code
- Process should be:
 - -Pragmatic
 - -Flexible
 - -Results oriented
- Will require code review
 - Which is a skill one must develop

Review Process Outline

- 1. Preassessment
 - Get high level view of system
- 2. Application review
 - Design review, code review, maybe live testing
- 3. Documentation and analysis
- 4. Remediation support
 - Help them fix the problems
- May need to iterate

Reviewing the Application

- You start off knowing little about the code
- You end up knowing a lot more
- You'll probably find the deepest problems related to logic after you understand things
- A design review gets you deeper quicker
 - So worth doing, if not already done
- The application review will be an iterative process

General Approaches To Design Reviews

- Top-down
 - Start with high level knowledge, gradually go deeper
- Bottom-up
 - Look at code details first, build model of overall system as you go
- Hybrid
 - Switch back and forth, as useful

Code Auditing Strategies

- Code comprehension (CC) strategies
 - Analyze source code to find vulnerabilities and increase understanding
- Candidate point (CP) strategies
 - Create list of potential issues and look for them in code
- Design generalization (DG) strategies
 - Flexibly build model of design to look for high and medium level flaws

Some Example Strategies

- Trace malicious input (CC)
 - Trace paths of data/control from points where attackers can inject bad stuff
- Analyze a module (CC)
 - Choose one module and understand it
- Simple lexical candidate points (CP)
 - Look for text patterns (e.g., strcpy())
- Design conformity check (DG)
 - Determine how well code matches design

Guidelines for Auditing Code

- Perform flow analysis carefully within functions you examine
- Re-read code you've examined
- Desk check important algorithms
- Use test cases for important algorithms
 - -Using real system or desk checking
 - -Choosing inputs carefully

Useful Auditing Tools

- Source code navigators
- Debuggers
- Binary navigation tools
- Fuzz-testing tools
 - Automates testing of range of important values
